IPv6 Addressing and Subnetting. Addressing and Subnetting in IPv6 is a bit different from IPv4. IPv4 organizes the address space in a couple of ways. First, IPv4 splits addresses by class, with classes A, B, and C defining unicast IPv4 addresses. Then, within the class A, B, and C address range, the Internet Assigned Numbers Authority (IANA) and the Internet Corporation for Assigned Names and Numbers (ICANN) reserve most of the addresses as public IPv4 addresses, with a few reserved as ...

a custom subnet mask. A custom subnet mask borrows bits from the host portion of the address to create a subnetwork address between the network and host portions of an IP address. In this example each range has 14 usable addresses in it. The computer must still AND the IP address against the custom subnet mask to see what the network portion is and

This calculator can be used for IPv6 in the same way VLSM is used to plan an IPv4 network. Remember, the size of IPv6 can be huge. This calculator can crash your browser if you attempt to have it calculate billions of subnets! Because of this, only the first 999 subnets are displayed. Use the above calculator to plan your IPv6 networks.

IPv6 Subnetting Workbook One of the design themes driving IPv6 was to keep subnetting as simple as possible. The forth hextet is reserved for subnetting, giving network administrators multiple options for developing a network plan. In order to keep IPv6 addressing as simple as possible it is a. Best Practice to subnet on the nibble boundary.

Class A address represents a very inefficient use of address space, since available Layer 2 technologies cannot easily support this many hosts on a single subnet. Subnetting uses this address space efficiently. Tech Tip IP version 6 (IPv6) is the next generation of IP addressing. IPv6

IP Addressing Guide - Cisco

To configure an IPv6 address on a Cisco interface you'll use the ipv6 address X:X:X::X/<0-128> command in interface configuration mode. Note that IPv6 addressing does not use a subnet mask explicitly following the address but uses the CIDR bit notation. Examples; IPv4 address 10.55.82.23 /24, IPv6 Address: 2001:dabd:32bf::1 /64.

The first 64 bits of any IPv6 address is the network ID, and the second 64 bits of any IPv6 address is the host ID. This means that any given IPv6 network has space for over 9 quintillion hosts. Still, sometimes network engineers might want to split up their network for administrative purposes.

The Subnet Prefix is the address space used by the Global Routing Prefix and the Subnet ID, and can range from 0 to 128. The preferred Subnet Prefix length is /48 to /64 for customers or sites. RFC 4291 recommends that the Interface-ID or host portion of your IPv6 address be 64 bits.
